

Sports Dataset Visual Story

IPL Performance Analysis Using Python

This project analyses IPL match data using Python, Pandas, Matplotlib and Seaborn. The objective is to clean the data, identify performance trends and communicate important findings through data visualization.

1. Dataset Summary

Total Matches: 577

Total Seasons: 9

Number of Teams: 13

Most Successful Team by Wins: Mumbai Indians

Top Player by Player of the Match Awards: CH Gayle

2. Matches Played per Season

Insight: The number of matches differs between seasons because tournament structures, participating teams and scheduling have changed over time.

3. Team Performance

Insight: The teams at the top have accumulated the highest number of victories, indicating strong long-term performance.

4. Player Performance

Insight: Players with many Player of the Match awards have repeatedly produced influential match-winning performances.

5. Toss Analysis

Insight: The toss winner also won approximately 50.43% of the matches in the dataset. Winning the toss therefore provides an opportunity but does not guarantee match victory.

6. Venue Analysis

Insight: A relatively small group of major cricket venues account for a large share of IPL matches.

7. Conclusion

The IPL dataset provides useful evidence about team success, player impact, toss decisions, venues and season-level trends. Data cleaning and visualization make these patterns easier to understand and communicate. The project demonstrates how Python-based data analysis can convert raw sports data into meaningful visual insights.
